(54) Title: NOVEL AMYLOLYTIC ENZYMES DERIVED FROM THE B. LICHENIFORMIS α -AMYLASE, HAVING IMPROVED CHARACTERISTICS (57) Abstract The present invention relates to novel amylolytic enzymes having improved characteristics for the use in starch degradation, in textile or paper desizing and in household detergent compositions. The disclosed α -amylases show surprisingly improved properties with respect to the activity level and the combination of thermostability and a higher activity level. These improved properties make them more suitable for the use under more acidic or more alkaline conditions. The improved properties allow also the reduction of the Calcium concentration under application conditions without a loss of performance of the enzyme.

Novel amylolytic enzymes derived from the *B.licheniformis*
 α -amylase, having improved characteristics

The present invention relates to amylolytic enzymes, particularly α -
10 amylases which are derived from such enzymes as present in *Bacillus*
licheniformis.

α -Amylases hydrolyse starch, glycogen and related poly-saccharides by
cleaving internal α -1,4-glucosidic bonds at random.

Starch consists of a mixture of amylose (15-30% w/w) and amylopectin
15 (70-85% w/w). Amylose consists of linear chains of α -1,4-linked glucose
units having a molecular weight (MW) from about 60,000 to about
800,000. Amylopectin is a branched polymer containing α -1,6 branch points
every 24-30 glucose units, its MW may be as high as 100 million.

Starch and especially derivatized starch or thinned starch are important
20 for a number of technical applications, e.g. as substrate for sugar and
alcohol production, as an intermediate in polymer production or as technical
aid during the production of textiles and paper. Starch is also the major
component of stains derived from e.g. chocolate, pap or porridge on clothes
and dishes.

25 Thinning of starch, also called liquefaction, is a first step which is
necessary in most applications of starch mentioned above. This thinning
step can be very conveniently carried out using α -amylase.

The α -amylase used thus far are isolated from a wide variety of bacterial,
fungal, plant and animal sources. The industrially most commonly used
30 amylases are those isolated from *Bacilli*.

A known drawback of enzymatic reactions is that enzymes are active
over a quite limited range of conditions such as pH, ionic strength and
especially temperature.

The α -amylase from *B.licheniformis* is one of the most stable ones in that
35 last respect known so far and is therefore used in applications where the

- 2 -

thermostability of the enzyme is crucial. However, the stability of this enzyme depends on the calcium concentration in the application and the optimum activity is observed at neutral pH. A more thermostable variant of the *B.licheniformis* enzyme, which has the same specific activity as the wild type enzyme, has been described in PCT/EP90/01042.

It has been shown in PCT/DK93/00230 that it is possible to improve the oxidation stability of *B.licheniformis* α -amylase by replacing methionines by one of the other 19 possible amino acids. In the specified test under the given conditions one of these mutants showed a slightly higher activity level than the wild type enzyme.

Though it has been shown that it is possible to improve the stability of amylolytic enzymes, in particular α -amylase, for some detrimental conditions, there is as yet no α -amylase available which has the same or better activity under suboptimal conditions than the wild type enzyme at optimum conditions. Suboptimal conditions are herein defined as conditions which use a pH other than neutral, e.g. lower than 6.5 or higher than 7.5, and/or conditions which use a lower than optimal Ca^{2+} concentration, i.e. lower than 50 ppm.

Because in most industrial applications the conditions are at best suboptimal, the problem of diminished activity could be solved by providing an enzyme which, at optimum conditions, has a higher activity than the wild type enzyme. It would then still have sufficient activity at sub-optimal conditions. The invention provides exactly such enzymes.

The invention provides an amylolytic enzyme derived from the amylolytic enzyme of *Bacillus licheniformis* or an enzyme having at least 70%, or preferably at least 90%, amino acid identity therewith which comprises at least one change of an amino acid in its sequence to another amino acid which provides the enzyme with a higher activity than the wild type enzyme. The activity of an amylolytic enzyme is herein defined as the specific activity as determined in Example 2. The higher activity of the mutant enzymes is apparent under optimal conditions but also under

- 3 -

suboptimal conditions where a pH value of less than pH 6.5 or higher than pH 7.5 and/or a Ca^{2+} concentration of less than 50 ppm is used. In addition, the invention provides such amylolytic enzymes with a higher thermostability than the wild-type enzyme, wherein the thermostability is defined as determined in Example 3. For some of the mutant enzymes, the improved thermostability is most pronounced under suboptimal conditions regarding the Ca^{2+} concentration.

The amino acid sequence of the *B.licheniformis* α -amylase is shown in Figure 1. The numbers indicate the position of an amino acid in the sequence and will be used as an indication for the amino acid position in the description of the amino acid changes. Regarding the corresponding amino acid changes in enzymes having at least 70%, or preferably at least 90%, amino acid identity with the *B.licheniformis* α -amylase, the skilled person will understand that the *B.licheniformis* α -amylase amino acid positions used herein refer to the corresponding conserved amino acids in the amino acid sequence of these related enzymes and not necessarily to their amino acid positions in those enzymes. It is also to be understood that these corresponding conserved amino acids are not necessarily identical to those of the *B.licheniformis* α -amylase.

In a site directed mutagenesis study we identified mutants on the amino acid sequence which influence the activity level of the enzyme. Among others, we made the following mutations: N104D, S187D, V128E and N188D, which are preferred mutant enzymes according to the invention. Some of these mutants showed a higher overall activity than the wild type enzyme. Alternatively, some of these mutations showed improved thermostability.

Although site directed mutations in the DNA encoding the amylolytic enzymes are a preferred way of arriving at the enzymes according to the invention, the man skilled in the art will be aware that there are different ways of obtaining the enzymes according to the invention and they are therefore part of this invention.

- 4 -

Due to the fact that until now only 3D-structure of non bacterial α -amylases are available (e.g. L. Brady et al. Acta Cryst. B47 (1991), 527-535, H.J. Swift et al. Acta Cryst. B47 (1991), 535-544, M. Quian et al. J. Mol. Biol. 231 (1993), 785-799), it is hard to predict for the α -amylase from *B.licheniformis* whether a certain amino acid at a certain position can have any influence on the activity level of the enzyme. One normally needs a 3D-structure for making such predictions, because the spatial orientation of the amino acids determines their role in the catalytic process. Without a 3D-structure of the investigated enzyme one has to relate the results of site directed mutagenesis experiments on putative active site residues on related enzymes (see e.g. L. Holm et al. Protein Engineering 3 (1990) 181-191, M. Vihinen et al. J. Biochem. 107 (1990) 267-272, T. Nagashima et al. Biosci. Biotech. Biochem. 56 (1992) 207-210, K. Takase Eur. J. Biochem. 211 (1993) 899-902, M. Sgaard et al. J. Biol. Chem. 268 (1993) 22480-22484) via a multiple sequence alignment (see e.g. L. Holm et al. Protein Engineering 3 (1990) 181-191) to the known 3D-structures. This allows the identification of the active site residues and allows to identify residues which are conserved in all similar enzymes. One normally assumes that conserved residues are crucial for the function or structure of the enzyme. It is therefore to be expected that mutations in those sites will influence the activity of the enzyme. By making mutations in said active sites it would therefore be expected that some mutations would result in higher activity. However, in *B.licheniformis* none of the mutated residues at position 104, 128, 187 and 188 are active site residues. Only position 104 is located at the end of a conserved region and could maybe be important for the activity, but also in that particular case a correct prediction of the effect of a point mutation is nearly impossible.

Another important aspect of the invention is the finding that in a number of cases the higher active mutants were slightly less thermostable than the wild type enzyme, except at least the mutations V128E and N188D, which are more stable, or at least more thermostable, than the wild type enzyme.

- 5 -

We therefore combined them with some earlier identified mutations which are known to stabilize the wild type enzyme. These are the mutations H133Y and T149I. These extra mutations indeed stabilized the more active mutants, but moreover they surprisingly showed an even higher activity level than the higher active mutants themselves.

In a further embodiment of the invention, the mutants of the invention are combined with mutations which improve the oxidation stability of the amylolytic enzyme. Such mutant enzymes may comprise mutations known in the art to improve the oxidation stability of amylolytic enzymes, such as e.g. mutations which replace the methionine at position 197 (see e.g. PCT/DK93/00230).

As stated before, a suitable way of arriving at the enzymes according to the invention is site directed mutagenesis of a nucleic acid, especially a DNA molecule, which comprises the coding sequence for the enzymes. The mutated nucleic acid molecules themselves are also part of the invention representing novel and inventive intermediates in producing the enzymes. Also by providing these nucleic acids in a suitable vector format (whereby a vector is meant to include any suitable vehicle for expression in a cell), it is possible to express the nucleic acid in a vast array of different hosts, including homologous and heterologous hosts, such as bacteria and/or other prokaryotes, yeasts, fungi, plant cells, insect cells or mammalian cells and or other eukaryotic host cells. These host cells which can be cultured to produce the enzymes are also part of the invention.

These cells can be cultured according to known techniques, which are all adapted to the particular kind of cell to be propagated. The isolation of the enzymes according to the invention from the culture or the culture supernatant is also known in the art.

A number of mutants will be more active (i.e. higher specific activity) and/or more stable (with respect to oxidation- and/or thermo-stability) even when only parts thereof are used. These fragments are of course within the

- 6 -

scope of this invention. It will also be possible to design mutations based upon this invention which have hardly any influence on the activity or stability, such derivatives are also a part of this invention. Some reactive residues which are present in the amino acid sequences according to the invention may also be chemically modified without having significant influence on the activity of such an enzyme. These derivatives are also a part of the invention.

The same may be stated for the nucleic acids according to the invention, which can be modified to a certain extent without influencing the important properties of the resulting enzyme. Therefore nucleic acid sequences which share at least 70% identity, or more preferably at least 90 % identity, with a coding sequence for an enzyme according to the invention or which are complementary to such a sequence are part of this invention. This is also true because based on this invention it will be possible to arrive at similar improvements in activity and/or stability in closely related enzymes such as amylolytic enzymes from *B.stearothermophilus* and *B.amyloliquefaciens*.

The novel amylolytic enzymes according to the invention may be used in all known applications of the amylolytic enzymes in the state of the art.

These applications include the use in the processing of starch, e.g. for polymer production wherein starch needs to be "thinned", the use in detergent compositions to break down stains which comprise starch or starch derivatives, the use in production of sugar or alcohol, or the use in the processing of textile or paper, in particular, the use for desizing of textile or paper, respectively.

Detergent compositions comprising the novel amylolytic enzymes are also a part of the invention. These compositions may be designed for dishwashing (either by hand or automatically), for household or industrial cleaning purposes, or for cleaning textiles. These compositions may comprise the usual additives and/or ingredients such as builders, surfactants, bleaching agents and the like.

- 7 -

Another preferred embodiment of the invention is the use of the enzymes in producing syrup or isosyrup from starch. Syrup and isosyrup are produced using an α -amylase according to the invention which catalyzes the liquefaction (or thinning) of the starch resulting in dextrins having an average polymerization degree of about 7-10, usually followed by saccharification of the liquefied starch resulting in a syrup with a high glucose content. Optionally the syrup can be isomerized to a dextrose/fructose mixture known as isosyrup.

The invention will now be explained in more detail through the following examples, which are intended for illustration purposes only.

- 8 -

ExamplesShort description of the figures:

5

Figure 1 gives the amino acid sequence of the α -amylase of *B.licheniformis*. The numbers relate to the positions of the amino acids in the sequence. They are used to identify the mutations, which are given in one letter amino acid code in the text of the application.

10

The nomenclature used for the mutations is as follows S187D means the replacement of the serine (Ser) at position 187 against an aspartic acid (Asp). Multiple mutants are designated as follows H133Y/T149I means the replacement of histidine (His) at position 133 by tyrosine (Tyr) plus the replacement of threonine (Thr) at position 149 by isoleucine (Ile).

15

Figure 2 gives a map of plasmid pBHATLAT. α -amylase: *B.licheniformis* α -amylase encoding gene. oripUB: origin of replication of plasmid pUB110. reppUB: replication protein of plasmid pUB110. neo: neomycin resistance gene. bleo: bleomycin resistance gene. pHpall: Hpall promoter. orifl: origin of replication of phage fl. ori322: origin of replication of plasmid pBR322. bla: β -lactamase (ampicillin resistance) gene. cat*: inactive chloramphenicol acetyl transferase (chloramphenicol resistance) gene. pTac: Tac promoter.

20

25

Example 1Production and purification of wild type and
mutant α -amylases**a) Genetic procedures:**

30

All molecular genetic techniques used for *E.coli* (plasmid construction, transformation, plasmid isolation, etc.) were performed according to

- 9 -

Maniatis et al. (Molecular Cloning, A Laboratory Manual, Cold Spring Harbor, 1989). Transformation of *B.subtilis* and plasmid isolation were performed according to Harwood et al. (Molecular Biological Methods for Bacillus, Chichester, 1990). *E.coli* strains containing pBHATLAT or its derivatives were grown in the presence of 100 mg/l ampicillin and 2 mg/l neomycin. *Bacillus subtilis* strains harboring pBHLAT 9-derived plasmids were cultivated in medium containing 20 mg/l neomycin.

Plasmid pBHA/C1 is a *Bacillus/E.coli* shuttle vector derived from the twin vector system pMa/c5-8 of Stanssens et al. (Nucl. Acids Res. 17 (1989): 4441-4454). A complete description of pBHA1 is given in the European Patent Application EP 414297.

The *B.licheniformis* α -amylase gene used throughout this study was obtained from plasmid pMcTLia6 (WO91/00353) as an EcoRI-HinDIII restriction fragment still including the inducible Tac promoter. This fragment was inserted in EcoRI-HinDIII digested pBHA1 to yield plasmid pBHATLAT (Fig. 2). This plasmid is used for the expression of α -amylase in *E.coli* through induction of the Tac promoter by 0.2 mM IPTG. Expression of mutant α -amylase was obtained by replacing the wild type α -amylase gene fragment by the corresponding mutant gene fragment. For expression in *Bacillus*, plasmid pBHATLAT was digested with BamHI and subsequent relegation thus placing the α -amylase gene under the control of the constitutive HpaII promoter. Wild type and mutant α -amylase enzyme was isolated from the *Bacillus* culture supernatant.

Site directed mutagenesis of the α -amylase gene was performed using the PCR overlap extension technique described by Ho et al. (Gene 77 (1989): 51-59).

b) Purification of the α -amylase wild type and mutants:

One aliquot of the culture supernatant is added to five aliquots water of 85°C and then maintained at 75°C for 15 minutes. Protease activity is removed in this step. The nzyme is then isolated via ion exchange

- 10 -

chromatography at pH 5.5 on a S-Sepharose FF column. The buffers used are 20 mM sodium acetate buffer with 1 mM CaCl_2 followed, with a gradient, by 20 mM sodium acetate buffer with 1 mM CaCl_2 and 0.5 M KCl. The pooled α -amylase fractions are concentrated by ultrafiltration via a 10 kD filter. By washing the concentrate with 1.6 mM EDTA in 50 mM MOPS, pH 7.5 the enzyme can be demetallized. Finally the concentrate is washed twice with 50 mM MOPS buffer pH 7.5.

Example 2

10 Determination of activity and enzyme concentration

The enzyme concentration is determined by measuring the optical density at 280 nm. The extinction coefficient of wild type enzyme is $135100 \text{ M}^{-1} \text{ cm}^{-1}$. The mutants with the mutation H133Y have an extinction coefficient of 136430 $\text{M}^{-1} \text{ cm}^{-1}$. The molecular weight is 55 kD.

The α -Amylase activity is determined by means of the substrate para-Nitrophenyl-maltoheptaoside (4NP-DP7). The reagent of Abbott (code LN5A23-22) is used. Besides 4NP-DP7 there is also α -glucosidase and glucoamylase in the substrate. α -Amylase activity is measured by the ultimate release of the chromophore p-nitrophenol (pNP).

The terminal glucose unit of the substrate is blocked with a benzylidene group. This terminal blocking inhibits cleavage by α -glucosidase until the initial bonds can be cleaved by α -amylase followed by glucoamylase.

The increase of the OD405 per minute is directly proportional to the α -amylase activity.

The molar extinction coefficient of pNP at 405 nm and pH 6.8 is $7600 \text{ M}^{-1} \text{ cm}^{-1}$. 1 Unit is 1 μmol converted substrate per minute. With the law "Lambert-Beer" the following relationship is established:

- 11 -

$$\text{Activity} = \frac{OD_{405} * 10^6}{\epsilon^{405} * l * t} = \frac{OD_{405}}{t} * 131.6 \left[\frac{U}{l} \right]$$

where t = time [minutes], l = lightpath [cm], ϵ^{405} = molar extinction coefficient at 405nm [$M^{-1} * cm^{-1}$], OD405 = extinction at 405 nm, 10^6 = calculation factor from mol/l \rightarrow μ mol/l

6 **Activity assay:**

- Add 0.8 ml reagent solution (R1) to a bottle R2 (Abbott).
- Heat the temperature controlled cuvette holder of the spectrophotometer to 37°C.
- Heat the activity buffer to 37°C (50 mM MOPS + 50 mM NaCl + 2 mM CaCl₂, pH 6.8).
- Add to the cuvette in the cuvette holder:
 - 500 μ l reagent
 - x μ l sample
 - 500 - x μ l activity buffer
- Measure the increase in extinction at 405 nm during 2 minutes.
- Calculate the activity by using the above equation.

Table 1

Specific activities of wild type (WT) and mutant α -amylases

Enzyme	Specific Activity [Units/mg]
wild type	60
H133Y	52
H133Y/T149I	60
N104D	30
N104D/H133Y	46
N104D/H133Y/T149I	52
V128E/H133Y	62
V128E/H133Y/T149I	54
S187D	110
H133Y/S187D	155
H133Y/T149I/S187D	150
H133Y/N188D	56
H133Y/T149I/N188D	52
V128E/H133Y/S187D	142

Example 3Determination of thermostability

The enzyme is incubated in an oil bath at 93 °C in closed Eppendorff micro test tubes with safety lid lock (order-No.: 0030 120.086). The Calcium concentration is varied whereas the ionic strength is kept constant. The buffer has at room temperature pH 7.5 which changes at the incubation temperature

- 13 -

to pH 7.0. A solution of $\pm 0,25$ mg/ml protein in 50 mM MOPS pH 7.5 is obtained by mixing the right amount of enzyme in 50mM MOPS pH 7.5 with X mM CaCl_2 + X mM K_2SO_4 + 100 mM MOPS pH 7.5 + water. The final buffer concentration must be 50 mM and the final volume should be 500 to 1000 μl (the best is 1000 μl). The salt composition is shown on the following table:

mM CaCl_2	mM K_2SO_4
0	15
0.25	14.75
0.5	14.5
0.75	14.25
1	14
1.25	13.75
1.5	13.5

Example for 0.5 mM CaCl_2 :

250.0 μl 100 mM MOPS pH 7.5

88.0 μl enzyme (1.42 mg/ml)

50.0 μl 5 mM CaCl_2

72.5 μl 100 mM K_2SO_4

39.5 μl demi water

500.0 μl total volume

The enzyme solutions are incubated in the sealed tubes at 93 °C. 50 μl samples are taken after 0.5, 10, 20, 30, 60, 90 and 120 minutes. The residual activity is determined with the Abbott Quickstart Amylase essay (see above). The half life time is calculated by using the fitting program GraFit (Leatherbarrow, R.J. 1990 GraFit version 2.0, Erithacus Softwar Ltd., Staines, UK).

- 14 -

Example 4**Starch liquefaction using a mutant α -amylase of the invention**

25 The mutant enzyme was proven to be effective in starch liquefaction tests using industrially relevant conditions. It was tested under identical conditions in comparison with the wild type enzyme.

- 15 -

A 34.3 % dry solids starch slurry was liquefied using a pilot plant jet cooking apparatus, Hydroheater Model # M 103-MS, at a flow rate of 2.8 l per minute. A 5 minutes retention time at 105 °C of primary liquefaction was followed by a 93 °C 120 min secondary liquefaction. The comparison tests vis a vis the wild type enzyme were performed based upon equal Modified Wohlgemuth Units (MWU) 168 units/gram of starch. The specific activity is for wild type 18,447 MWU/mg and for H133Y/S187D 48,000 MWU/mg respectively.

The enzymes were tested under two sets of conditions. The first experiment used standard industrial conditions (pH 6.4, 44 ppm Calcium), while the second experiment employed stress conditions (pH 5.8, 8 ppm Calcium).

The decrease in viscosity during liquefaction was measured with a #3 Zahn cup, while Dextrose Equivalent (DE) development was measured using a reducing sugar assay. The results are summarized in the following tables:

Table 3.

Experiment 1: pH 6.4, 44 ppm Calcium

time (min)	Wild type		H133Y/S187D	
	DE	Viscosity	DE	Viscosity
0		25		24
20	2.7		2.4	
40	4.0		3.5	
60	5.4	14	4.7	14
80	6.5		6.0	
100	7.8		7.5

Example 5Textile desizing using a mutant α -amylase of the invention

Cretonne cotton patches (30 * 30 cm, J. Hacot et Cie., 48 Rue Mermoz, La Gorgue, France) are impregnated with 12 % soluble starch (weight/weight) as sizing agent. The sized cotton is given in a beaker with one litre tap water and 0.5 ml/l wetting agent at 25 °C and pH 7.0. α -Amylase is added in a concentration as shown in the table. The mixture is agitated and heated with a gradient of 2 °C per minute within 30 minutes to a final temperature of 85 °C. After 10 minutes agitating at the final temperature the fabric is 2 minutes rinsed with cold water and dried.

The residual starch is determined with a reflectometric method. The residual starch on the fibres is coloured with a solution made from 0.15 g iodine, 0.5 g potassium iodine and 10 ml 2 N H₂SO₄ in a volume of 1 l water. The dried cotton patch is wetted with alcohol and s aked in th colouring

- 17 -

solution for 15 minutes. The reflectance of the coloured patch is measured at 700 nm with a Universal Messeinheit UME 1 III/LR 90 reflectometer (Dr. Bruno Lange GmbH, Berlin, Germany). The amount of residual starch can be calculated with a calibration curve recorded with known amounts of starch on the fabric.

Table 5.

A comparison of the performance of the wild type and a mutant α -amylase in the desizing of textile.

wild type		H133Y/S187D	
enzyme concentration [μ mol/l]	remaining starch on fabrics [mg/g]	enzyme concentration [μ mol/l]	remaining starch on fabric [mg/g]
0	3.92	0	4.05
9.3	3.35	2.5	3.35
18.5	2.76	4.9	2.45
37.2	2.25	7.6	2.02
46.5	1.85	9.1	1.72
70	1.42	12.5	1.37
93	0.9	18.9	1.12
		25.3	0.68
		37.8	0.5

- 18 -

Example 6A comparison of the wash performance of the wild type
and a mutant α -amylase

- 5 The wash performance of the wild type vis a vis the H133Y/S187D mutant was tested in a full scale wash experiment using the amylase sensitive cotton test fabric EMPA 112 as monitor. In all tests the α -amylase dosage was 1.3 mg/l suds. A blank was taken as reference. Washing powder base was the IEC reference detergent A, containing bleach and protease.
- 10 All tests were carried out in quintuple. The fabrics were washed in a Miele, type W701 washing machine at 40 °C and a total load of 4 kg fabrics. The soil removal was determined by measuring the white light reflection with a Colorgard Model 05 (Gardner Lab., USA) reflectometer. Table summarizes the results. It shows that the mutant performs better than wild type enzyme at
- 15 the same dosage.

Table 6.

A comparison of the wash performance of the wild type and a mutant α -amylase

20	Enzyme	none	wild type	H133Y/S187D
	Soil removal	31.7 %	40.2 %	42.1 %

Claims

1. An amylolytic enzyme derived from an α -amylase of *Bacillus licheniformis* or an enzyme having at least 70% amino acid identity therewith which comprises one or more amino acid changes at positions selected from
5 the group consisting of positions 104, 128, 187 and 188 of the amino acid sequence of the α -amylase of *Bacillus licheniformis*.
2. An enzyme according to claim 1, wherein one or more of the amino acid changes are selected from the group consisting of Asn at position 104 to
10 Asp, Val at position 128 to Glu, Ser at position 187 to Asp, and Asn at position 188 to Asp.
3. An enzyme according to any one of claims 1 or 2, which comprises at least one additional amino acid change providing the enzyme with improved
15 thermostability.
4. An enzyme according to claim 3, wherein at least one additional amino acid change selected from the group consisting of His at position 133 to Tyr, and Thr at position 149 to Ile.
20
5. An enzyme according to any one of claims 1-4, which comprises at least one additional amino acid change providing the enzyme with improved oxidation stability.
- 25 6. An enzyme according to claim 5, wherein the additional amino acid change comprises a change of a methionine to another amino acid.
7. An enzyme according to claim 6, wherein the methionine is the methionine at position 197.
30

- 28 -

8. A nucleic acid molecule encoding an enzyme according to any one of the claims 1-7 or a nucleic acid complementary to said nucleic acid or a nucleic acid which hybridizes to either of said nucleic acids under moderately stringent conditions.

5

9. A vector for expression of an enzyme according to any one of the claims 1-7, comprising a nucleic acid according to claim 8, together with suitable elements for expression.

10 10. A cell for expressing an enzyme according to any one of claims 1-7, comprising a nucleic acid molecule or a vector according to claims 8 or 9, respectively.

11. A process for producing an enzyme according to any one of claims
15 1-7, which comprises culturing a cell according to claim 10 in a suitable medium for expression of said enzyme and after a suitable amount of time isolating the enzyme from the culture or the culture supernatant.

12. Use of an enzyme according to any one of the claim 1-7 in the
20 processing of starch, in the production of syrups, isosyrups, or ethanol, in the desizing of textiles or paper, in brewing processes, in detergents or in the beverage industry.

13. A detergent composition comprising an enzyme according to any
25 one of claims 1-7.

(54) Title: NOVEL AMYLOLYTIC ENZYMES DERIVED FROM THE B. LICHENIFORMIS α -AMYLASE, HAVING IMPROVED CHARACTERISTICS

(57) Abstract

The present invention relates to novel amylolytic enzymes having improved characteristics for the use in starch degradation, in textile or paper desizing and in household detergent compositions. The disclosed α -amylases show surprisingly improved properties with respect to the activity level and the combination of thermostability and a higher activity level. These improved properties make them more suitable for the use under more acidic or more alkaline conditions. The improved properties allow also the reduction of the Calcium concentration under application conditions without a loss of performance of the enzyme.

INTERNATIONAL SEARCH REPORT

International Application No

PCT/EP 95/01688

A. CLASSIFICATION OF SUBJECT MATTER

IPC 6 C12N9/28 C12N15/56 C12N15/75 C12P19/14 C11D3/386
D06M16/00 C12S11/00 //D06M101:04

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C12N C12P C11D D06M

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	FR,A,2 676 456 (INSTITUT NATIONAL DE LA RECHERCHE AGRONOMIQUE) 20 November 1992 see the whole document ---	1-3, 5, 8-13
X	WO,A,94 02597 (NOVO NORDISK) 3 February 1994 see the whole document ---	1, 5, 8-13
X	WO,A,91 00353 (GIST-BROCADES) 10 January 1991 cited in the application see the whole document ---	1-3, 5, 8-13
P, X	WO,A,94 18314 (GENENCOR INTERNATIONAL INC.) 18 August 1994 see page 64 - page 68 -----	1-13

☐ Further documents are listed in the continuation of box C.☒ Patent family members are listed in annex.

* Special categories of cited documents:

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

Z document member of the same patent family

Date of the actual completion of the international search

14 December 1995

Date of mailing of the international search report
